HARiS - HIV and AIDS Response Indicator Survey 2014 for Male Clients of Female Sex Workers

Background

HIV behavioural surveillance among at risk target populations is an essential tool in measuring HIV behavioural risk factors and providing information of the effectiveness of programmes and interventions in preventing HIV infection. To better understand the risk of HIV infection among the male clients of female sex workers (MCFSW) population, it was included as one of the four major at-risk populations in the HIV/AIDS Response Indicator Survey (HARiS) implemented since 2013. The survey was repeated in 2014 via commissioning to the Stanley Ho Centre for Emerging Infectious Disease, School of Public Health and Primary Care of the Chinese University of Hong Kong.

The aims of HARiS survey were to establish a community-based behavioural survey with collection of standardized strategic information; to provide data of a pre-defined set of core indicators among the major at-risk subpopulations for surveillance of HIV-related risk behaviours and HIV testing patterns; and to enable the indicators to be tracked and compared over time for evaluation of the coverage and effectiveness of health-promotion and surveillance programmes in Hong Kong.

Methods

Participants were recruited via centre-based HIV Voluntary, Counselling and Testing (VCT) services (by 4 NGOs) or during the outreach sessions (by 1 NGO) from February to August 2014. Any male who had patronized a female sex worker in the preceding year was eligible to complete a self-administered questionnaire.

Results

A. Characteristics of the participants

A total of 579 participants (centre-based: 319; outreach: 260) were recruited from the supporting NGOs. A majority of them (94.3%) had stayed in Hong Kong for more than 3 months in the preceding 6 months. Nearly all of them (98.8%) were Chinese. Nearly half (48.4%) were married and 56.5% were younger than 40 years old.

B. Sexual behaviours with female sex workers

Among all 579 participants, 490 (84.6%) had had vaginal sex with a female sex worker (FSW) within last 6 months. 55.6% and 41.3% had their last sex with FSW in Hong Kong and Mainland China respectively. The most commonly reported type of FSW last patronized were one-woman brothel (31.8%), night clubs/Karaoke (22.1%) and massage parlor/foot massage (19.2%). Overall, 88.1% had used a condom in their last vaginal sex with a female sex worker.

C. Sexual behaviours with regular and non-regular sex partners

67.4% had had vaginal sex with a regular sex partner (RSP) in the preceding 12 months. A majority of them (81.5%) had the last sex episode in Hong Kong. The condom use rate in last vaginal sex with an RSP was 58.5%.
In the past year, more than one-fourth of the participants (26.4%) had had vaginal sex with a non-regular sex partner (NRSP). Over half of them (65.4%) had their last sex in Hong Kong and the condom use rate in last vaginal sex was 74.5%.

D. HIV testing behaviours

Of all 579 respondents, 311 (53.7%) had ever had a HIV test and 287 (49.6%) knew their last test results. However, only 216 (37.3%) had their last tests done in the past 12 months, and 206 (35.6%) knew the test results. Most of them had their last tests done at public hospital/clinic (42.8%) and NGO VCT sites (42.8%), followed by private doctors (10.9%).

Discussions

1. The survey showed that more than two-fifths of the respondents (41.3%) had patronized FSW in the Mainland, which was comparable to the previous findings of 41.6% in HARiS 2013. The situation should be closely monitored as cross-border sexual activity and also the HIV situation of neighbouring Mainland cities could affect the local HIV epidemiology.

2. MCFSW can serve as a potential bridge for HIV transmission between FSW and the general population. Given that last condom use rate with regular and non-regular sex partners (58.5% and 74.5%, respectively) are relatively low among MCFSW from the survey, promotion of safer sex practice in all partner types has to be continued.

3. The overall HIV testing rate (53.7%) and HIV test in last 12 months (37.3%) showed slight improvement compared with figures from HARiS last year (45.9% and 29.6%). However, they were still low when compared to other at-risk populations. This suggested that HIV testing is not yet a norm among this target group and promotion of HIV testing should be strengthened.
