# SURVEILLANCE OF VIRAL HEPATITIS IN HONG KONG

## 2017 UPDATE

### ACKNOWLEDGEMENTS

The Special Preventive Programme wishes to thank the following agencies for their contributions to the preparation of the 2017 Update Report:

Action for REACH OUT

CHC-Group Medical Practice

Chinese University of Hong Kong

Department of Medicine, Princess Margaret Hospital

Department of Microbiology, Prince of Wales Hospital

Department of Microbiology, Princess Margaret Hospital

Family Health Service, Department of Health

Family Planning Association of Hong Kong

Public Health Laboratory Services Branch, Centre for Health Protection, Department of Health

Health Service of Baptist University of Hong Kong

Hong Kong Red Cross Blood Transfusion Service

Hong Kong Cancer Registry

Pamela Youde Nethersole Eastern Hospital

Surveillance & Epidemiology Branch, Centre for Health Protection, Department of Health

TB and Chest Service, Centre for Health Protection, Department of Health

The University of Hong Kong

# SURVEILLANCE OF VIRAL HEPATITIS IN HONG KONG

## 2017 UPDATE

### COMMENTARY

#### Surveillance Mechanisms of Viral Hepatitis in Hong Kong

1. Viral hepatitis is a statutory notifiable disease in Hong Kong. Locally, voluntary reporting was started in as early as 1966 and, since 1974, the disease has become notifiable. It was not until 1988 that the reported cases were classified by viral etiology, namely hepatitis A, hepatitis B, non-A non-B hepatitis and unclassified hepatitis. In 1996, non-A non-B hepatitis was further categorised into hepatitis C, hepatitis E and hepatitis (not elsewhere classified).

2. The extent of chronic infections resulting from some hepatitis, notably hepatitis B and C, is determined by other mechanisms. Insight into the epidemiology of various forms of hepatitis in Hong Kong can be gained by analytical interpretation of regular statistics collected by health care or other institutions, and information generated from various studies. This Report presents the latest findings from collation and analysis of viral hepatitis data obtained from the disease notification system, service statistics, seroprevalence studies and other research findings. Much as one hopes that the local viral hepatitis picture can be painted accurately and fully, this is certainly limited by the nature and availability of data. The presence of biases in data *per se* and their interpretation need to be acknowledged in reading this Report.

#### Epidemiology of HAV and HEV

3. Hepatitis A virus (HAV) and hepatitis E virus (HEV) are both transmitted by the faecal-oral route, albeit with different local epidemiology in the past two decades. Hong Kong was once of intermediate endemicity for HAV [1, 2]. After 1988 when viral hepatitis began to be reported according to etiologic agents, the largest epidemic of hepatitis A occurred in 1992, with over 3,500 cases reported to the Department of Health (DH) (Box 1). This represented a notification rate of 63 per 100,000 population (Box 7) and since then, a gradual declining trend in HAV incidence has been observed. This discernible decline in hepatitis A contributed to a parallel declining trend in overall

reported viral hepatitis since 2002 (Box 3). The case fatality rates from hepatitis A has been low and ranged between 0 and 0.15% in the last two decades (Box 7).

4. From 2008 to 2017, the annual number of hepatitis A cases reported ranged from 43 to 138 (Box 1). In 2015, a review on 587 reported cases of hepatitis A from 2005 to 2014 was published by the Surveillance and Epidemiology Branch (SEB) of Centre for Health Protection (CHP), Department of Health (DH). The male to female ratio was 1.2 to 1, with 75% aged below 40 years. The majority (70%) of cases required hospitalisation, and two fatal cases were recorded. Both fatalities had multiple comorbidities. The majority (76%) of the patients acquired the disease locally. 92% were sporadic cases and 22 small clusters affecting two to four patients were identified, at least 60% of which were clusters affecting members of the same household [3].

5. An increase in the number of cases was noted in 2015 when a total of 138 cases were reported. The majority (75%) of the cases was reported from February to June. The male to female ratio was 1.2 to 1, with a median age of 33 years (range: 3 to 83 years). There was no fatality. Except two cases studying in the same school and two cases from same family, no epidemiological link was found. No single identifiable source could explain the upsurge of cases [3].

6. In 2016, a total of 98 cases of hepatitis A were recorded, affecting 68 men and 30 women (male to female ratio 2.26:1) aged from 3 to 86 years (median 32 years). Sixty-three cases (64.3%) acquired the infection locally. 85.7% required hospitalisation.

7. In late 2016, an unusual upsurge of acute hepatitis A infection affecting men who have sex with men (MSM) with human immunodeficiency virus infection was noticed. With retrospective investigations and prospective reporting, a total of 53 cases of laboratory-confirmed HAV infection with clinical symptoms among individuals identified as MSM were recorded between September 2015 and November 2017. The age range was 20 to 55 years (median: 33 years). Forty-five (84.9%) required hospitalisation and there were no fatalities. Thirty-seven cases (69.8%) were known to be HIV-positive attending one of the three designated public HIV clinics. The majority (96.2%) did not report history of HAV vaccination. Eighteen (33.9%) reported travel history within the incubation period. Around one quarter of the cases had concurrent diagnosis of other sexually transmitted infections including syphilis, gonorrhoea and chlamydia infection. Among the cases with specimen available for laboratory analysis, forty-three (81.1%) had identical nucleotide sequences within the

genotyping window. Apart from one cluster affecting two patients who were sex partners residing together, no other epidemiological linkage could be found. No common food nor water source or social gathering was identified among these cases. Epidemiological investigations suggested that the outbreak was contributed by transmission by way of sexual contact between men, a high proportion of whom were HIV-infected. HAV outbreaks among MSM communities were being reported during the same period in some other regions with low HAV endemicity including Taiwan, Europe and both North and South America [4].

8. Over the years, there has been an increase in the proportion of reported cases over 35 years old. Although the majority were still below 44 years of age, the proportion of reported cases that were aged 45 and above had increased from less than 10% in the last two decades to 14%-25% since 2010 (Box 6).

9. In a local household study conducted in 2001, (Community Research Project for Viral Hepatitis 2001, CRPVH), anti-HAV positivity was less frequent ( $P < 0.001$ ) across all age groups among subjects  $> 21$  years old [2] than subjects in the same age groups of another study conducted in late 1980s [5]. HAV prevalence has only increased insignificantly in every 10-year age groups of people aged 21-50 when compared with their corresponding 10-year younger age groups, signifying an aging cohort effect with no major infections in the prior 10 years [2]. Similar conclusions can be drawn when comparing the late 1980s findings with those of a late 1970s study on local HAV seroprevalence [6]. Together, these three studies suggest that age-specific prevalence of HAV has right-shifted locally since 1980s. As of 2001, anti-HAV was present in about 20% of adults below 30 years old while it was over 80% in people aged  $\geq 40$  years in the general Chinese population (Box 20). Data from laboratory surveillance performed by Public Health Laboratory Services Branch (PHLSB) every five years had also shown that the seroprevalence of anti-HAV had remained below 40% among those younger than 30 years old in 2000, 2005 and 2010. From the available data, the prevalence of hepatitis A infection has been falling in Hong Kong, which echoes the finding of a higher median age in reported HAV cases that also reflects the increased susceptibility of the adult population. The data also indicates that Hong Kong has changed from a region with intermediate to very low endemicity in the past three decades (Box 21) [7].

10. Besides an increasing prevalence with higher age, people born outside Hong Kong were generally more likely to test positive for anti-HAV whereas the reverse was true for people of non-labour work [2]. From the telephone interview part of the CRPVH 2001, some 11% of 4,564 subjects reported a history of HAV vaccination, about 80% of whom had completed the course. More people less than 40 years old had received the vaccination. Over 98% had the cost paid by themselves or covered by their employers. In the latest serosurvey conducted by PHLSB in 2015, there was a significant increase in the seroprevalence of anti-HAV in the younger age group, most prominent among those aged 0-10 (Box 21). These findings may suggest an increase in uptake of HAV vaccination in the community.

11. Cross-sectional surveys of anti-HAV at Kowloon Bay Integrated Treatment Centre (ITC), the HIV specialist clinic under Department of Health, have been started since 2007. The subjects consisted of all new HIV/AIDS patients who first attended ITC between Jul 2007 and 2017 and convenience samples of all active HIV/AIDS patients who first attended ITC before Jul 2007 (Box 22). The prevalence of anti-HAV increased with age of HIV/AIDS patients, and the overall positivity rate among these patients tested between 2007 and 2017 appeared to be comparable with that of the 2010 serosurvey data. Confounding factors, such as different levels of past infection, immunodeficiency in HIV patients, history of HAV vaccination and difference in years of testing, may have affected the results. Compared with patients acquiring HIV via other routes, those infected via homosexual or bisexual routes were at the highest risk of hepatitis A infection, as reflected by the lowest level of anti-HAV prevalence in this group of patients (Box 23). Indeed, the increased susceptibility had manifested itself during the upsurge of hepatitis A infection among MSM occurring in 2015 to 2017 [4]. As a result, the Scientific Committee on AIDS and STI, and Scientific Committee on Vaccine Preventable Diseases had extended their recommendation for hepatitis A vaccine to MSM in June 2017 [8].

12. The annual notification of hepatitis E infection increased from 11 in 1996 to a record high of 150 in 2012 (Box 1). In the past five years, the number of reported cases of hepatitis E ranged from 64 to 96. A seasonal pattern was observed with peak infections reported from February to April (Box 15), indicating that infection was more common during winter and spring seasons. Of 1271 cases reported, 838 (65.9%, Box 16) were male, giving male to female ratio of 1.9:1. The majority was adults, most of whom were aged between 35 to 74 (Box 17). Fatalities were more common with acute

hepatitis E than with acute hepatitis A and the death rate reached as high as 0.44 per million population in 2002 when three deaths attributable to acute hepatitis E infection had occurred (Box 18).

13. In the CRPVH study conducted in 2001, 18.8% of adult subjects were found to have serologic evidence of HEV infection. People in the 40-49 years age group had the highest positivity rate of 24.1% (Box 24). Another local seroprevalence study on anti-HEV using 450 serum samples submitted for virological investigation in 2008-2009 in a local hospital found a higher rate of HEV IgG seropositivity [9]. The HEV IgG seropositivity rate increased from 8% among 1-10 years old to >56% among those aged over 80. The overall seropositivity rate was higher among male than female (32.9% vs 24.4%,  $p=0.048$ ). Despite the limitations of small sample size and bias sampling in this study, the finding of an overall increase in the seropositivity rate is compatible with the changing local epidemiology of Hepatitis E notified to Department of Health in recent years.

14. The CHP reviewed all hepatitis E cases recorded between 2001 to 2010 [10]. Of the 524 cases, the commonest presentations were tea-coloured urine, jaundice, anorexia, fever, myalgia and nausea. 78.2% were hospitalised with a median stay of 7 days. A total of 12 cases were fatal (9 males and 3 females), age ranged from 53 to 82 (median age 67.5 years). The case fatality rate was 2.3%, which was comparable with reported figures from other countries. None of the fatal cases were pregnant. Most cases (99.4%) were sporadic infection and 87.4% acquired the disease locally. A small family cluster involving 2 males (aged 15 and 44 years) was identified. The 2 victims had shared multiple high-risk food items at home during the incubation period. It proved difficult to determine the exact source of infection of individual sporadic cases as hepatitis E has a long incubation period of 15-64 days. Nonetheless, epidemiological investigation has not identified any outbreak linked to a particular food premises.

15. Another review of the acute hepatitis E cases recorded by CHP from 2012 to May 31 2017 showed a total of 554 cases, with age ranging from 15 to 96 years (median: 55 years) [11]. More males were affected than females (63.0% vs. 37.0%). More cases were recorded in February and March. Most of the cases (83.8%) acquired the infection locally. Symptomatology was similar with the cases from 2001 to 2010. Four hundred and seventy-six (85.9%) patients required hospitalization with a median length of stay of six days. Nine fatal cases were recorded, among whom 7 had

underlying illnesses, giving a case fatality rate of 1.6%. The age of the deceased patients ranged from 59 to 79 years (median: 74 years). All cases were sporadic infections, except for a pair of father and son who shared meals frequently during the incubation period. None of the cases was related to outbreak involving food premises. A significant proportion of the victims recalled consuming pig offals (37.5%) and shellfish (29.4%) during the incubation period.

16. Another published study identified differences in epidemiology and clinical features between sporadic hepatitis E and hepatitis A cases. Of 105 acute hepatitis A and 24 hepatitis E patients seen at Princess Margaret Hospital (PMH) in 2002, HAV patients were significantly younger (median age of 27 years) and had recent history of shellfish consumption while HEV patients were older (median age = 53 year) and most had a recent travel history. Moreover, whereas hepatitis A was milder and recovery was uneventful, hepatitis E was more severe, associated with significant mortality and frequently complicated by protracted coagulopathy and cholestasis [12].

17. A local study examined the genotype of 57 patients with acute HEV infection who were admitted to Prince of Wales Hospital (PWH). Fifty-six patients (98%) were Chinese. All cases were sporadic. No fulminant hepatitis was recorded and all patients recovered. Phylogenetic analyses of the open reading frame ORF2 fragments from 46 patients and ORF1 fragments from 33 patients showed complete agreement, with most (n= 45 [98%]) belonging to genotype 4. The remaining isolate was genotype 3 obtained from a woman who had no history of travel. Most of the Hong Kong isolates clustered closely with a swine isolate reported from Guangxi Province, China [13].

18. Apart from pregnancy, coinfection with chronic Hepatitis B virus might be associated with more fulminant clinical outcome in patients infected with Hepatitis E. Among 3 cases of serious infection of Hepatitis E with acute liver failure reported to DH in the first two months of 2012, one required liver transplantation and two passed away. One of the deceased patients was tested positive for chronic hepatitis B infection [14]. Moreover, a 10-year retrospective study on acute hepatitis E in local hospitals showed that patients with chronic HBV acutely infected with hepatitis E had a higher rate of liver failure, liver-related mortality and all-cause mortality, though the association was not statistically significant [15].

19. There is evidence suggesting a zoonotic source of Hepatitis E in overseas studies, and that pigs may be an important reservoir. In light of these observations, the Centre for Food Safety conducted a risk assessment study titled "Hepatitis E Virus in Fresh

Pig Livers” [16] to determine the HEV prevalence in fresh pig liver samples obtained in local markets. One hundred fresh pig liver samples were collected from pigs slaughtered between mid-January and May. Sixteen (31%) out of 51 roaster pig (around four months old) liver samples were positive for HEV, while none of the 49 porker pig (around six months old) liver samples tested positive. Partial sequences of some HEV isolates from roaster pigs were identical to those from 7 among 48 local human cases with date of onset from January to July 2009, as well as local cases recorded in the past. The findings suggest the possibility of roaster pigs as one of the sources of local human hepatitis E infections.

20. One HEV vaccine was licensed in China in December 2011 for use in people aged at or older than 16 years old [17]. To date, it has not been licensed in other countries or territories. It has been shown to have high efficacy against hepatitis E in healthy adults of 16 to 65 years old in China. Data is however limited on its impact on the overall disease incidence and reduction of mortality in the general population where disease is endemic. Therefore, in the absence of sufficient information, World Health Organization (WHO) has not made recommendation on its incorporation in national programmes [17].

### **Pattern of Hepatitis B in Various Communities and its Significance**

21. The number of reported acute hepatitis B virus (HBV) infections has been decreasing over the last decade, from 137 cases reported in 2000 to 33 cases reported in 2017 (Box 1). In an epidemiologic study of acute HBV by the Department of Health and Hong Kong Red Cross Blood Transfusion Service (HKRCBTS), 149 of 351 eligible subjects recruited from 2000 to 2003 participated in risk factor assessment with or without blood screening. Repeat blood donors who tested positive for HBsAg for the first time and were then confirmed IgM anti-HBc positive were reported as having acute HBV. There were 43 such clients, yielding an incidence rate of HBV seroconversion in repeat donors as 9.4/100,000 (n=148,366), 9.3/100,000 (n=150,420), 4.6/100,000 (n=151,410) and 3.5/100,000 (n=143,230) in 2000, 2001, 2002 and 2003 respectively. Nearly 70% of the study subjects were male; 99% were Chinese and the mean age was 31 years. Over half could not have risk factor of acute HBV determined despite undergoing a standardised questionnaire interview by nurses. Sexual contact was assessed to be the commonest risk (85%) in the rest. Of 124 subjects who had hepatitis B screening at 6 months post-IgM anti-HBc positivity, 50% developed anti-HBs while 9.7% were HBsAg positive. Although these results could suggest a higher

rate of HBV chronicity than what was previously reported in the literature, they have to be interpreted with caution owing to the relative small number of samples, incompleteness of data and potential biases from the subjects sampling and other study design.

22. Determining the seroprevalence of hepatitis B surface antigen (HBsAg) sheds light on how common chronic HBV infection is in different communities, as well as informing its chronic disease burden. The various adult communities can be categorised into 3 groups according to the risk of contracting HBV:

- (a) without apparent risk: blood donors, pre-marital/ pre-pregnancy service users, antenatal women, police officers, new health care workers (HCW)
- (b) with undetermined risk: clients seeking post-exposure management and tuberculosis patients
- (c) with apparent risk: drug users, HIV/AIDS patients and female sex workers

23. A majority of the available seroprevalence data in different populations were limited to overall positivity rate of HBV markers. Still, temporal trend can be discerned as most have yearly data for the past decade or so. Several features on the current pattern of HBV could be observed from the serologic investigations, namely

- (a) chronic HBV infection is in a general declining trend in community groups without apparent risk of contracting HBV
- (b) HBV prevalence increases with increasing age, and
- (c) chronic HBV infection is commoner in male than female.

24. A word of caution in the interpretation of data though, is that testing for HBV markers has been performed for a variety of reasons in different communities, with heterogeneous mix of population characteristics.

### **Seroprevalence of adult communities without apparent risks**

25. The temporal decline of chronic HBV infection has been most obvious in new blood donors and police officers. For new blood donors, the HBsAg prevalence follows a continual falling trend since early 1990s, from 8% in 1990 to 0.9% in year 2017 (Box 25). The trend is even more obvious among the 16-19 years age group where the prevalence is as low as 0.3% in both female and male (Box 26). A similar trend was observed among police officers where the HBsAg prevalence falls from 7.9% in 1997

to 1.4% in 2017 (Box 32), with the lowest prevalence of 0.5% among those aged 20 or less (Box 33). A falling trend was also observed in other community groups without apparent HBV risk, albeit less prominent (Box 42, 43).

26. The HBsAg prevalence in antenatal mothers has been decreasing from over 10% in the early 1990s to 5.0% in 2017 (Box 29). As compared with other groups without apparent risk, the overall HBsAg prevalence in antenatal mothers is higher and confounded by the place of birth. A study of 2480 pregnant women attending the Maternal and Child Health Centre (MCHC) of DH in 1996 found a 13.1% in those born in Mainland China as compared to 8.4% in local mothers [18]. Data from Virus Unit, Department of Health also showed a higher prevalence of 12.5% and 13.8% in the subset of non-resident expectant mothers versus the overall positivity rate of 8.5% and 8.6% in 2004 and 2005 respectively. The prevalence in pre-marital/ pre-pregnancy package service users has dropped from 9.6% in 1990 to remain static in the range of 4.8% to 6.9% in the past decade (Box 28). The prevalence in newly recruited health care workers as determined at pre-HBV vaccination screening also showed a decreasing trend from 5.9% in 2001 to 3.5% in 2017 among female, and from 6.1% in 2001 to 2.4% in 2017 among male (Box 35).

#### **Seroprevalence of adult communities with undetermined risk**

27. Of 874 tuberculosis patients attended TB & Chest Clinics, DH between March and May in 2015, 74 (8.5%, Box 36) were detected HBsAg positive, with the highest prevalence rate in the middle age group (40-59 years old: 10%, Box 37) followed by the more elderly group ( $\geq 60$  years old: 8.8%, Box 37). The HBsAg positivity rate was also found to be higher in male clients (10%) than in female (5.7%, Box 36). Both the age (Box 37) and gender pattern (Box 36) were consistently observed over the last decade. Among clients attended for post exposure management, HBsAg rate was found higher in non-health care workers than in health care workers (Box 38), which may be partly explained by the success of pre-employment vaccination programme for healthcare workers.

#### **Seroprevalence of adult communities with apparent risk**

28. The HBsAg prevalence in HIV/AIDS patients under care of DH was in the range of 5.6% to 11.3% in the past decade (Box 40). Due to underlying immunosuppression and shared routes of transmission, HIV/AIDS patients are more likely to be chronically infected with HBV [19]. The HBsAg prevalence in female sex workers attending the

clinic of Action for REACH OUT tested between 2007 to 2011 ranged from 5.0% to 10.4% (Box 43). The data regarding prevalence of HBsAg in drug users was difficult to interpret because of the small number of subjects since 2006 (Box 39). Overall, the difference in HBsAg prevalence between groups with or without apparent risk of contracting HBV has not been prominent in the past few years.

### Genotypes of Hepatitis B and their Disease Course

29. Different HBV genotypes have been identified with distinct geographic distribution and association with different clinical outcomes. Local studies indicated that genotype C was the commonest genotype and genotype B was the second. A study of 776 chronic hepatitis B patients seen at the University of Hong Kong Liver clinic from 1999 to mid-2003 found that genotype C was the commonest (486, 62.6%), followed by genotype B (252, 32.5%), with a majority of genotype B belonged to subgroup Ba [20]. Another study of 426 chronic HBV patients recruited consecutively from 1997 to mid-2000 at the Hepatitis clinic of Prince of Wales Hospital (PWH) found a prevalence of 57% (242) and 42% (179) of genotypes C and B respectively [21].

30. A study of 49 HBV genotype C ethnic Chinese patients under the care of the PWH Hepatitis Clinic identified 2 distinct groups with different epidemiological distribution and virologic characteristics – 80% being genotype “Cs” (found mostly in Southeast Asia) and 20% “Ce” (predominated in Far East) [22]. In addition, subgenotype Cs appears to be more common in Hong Kong than other parts of China. In the recent analysis of a cohort of patients with HBeAg-negative chronic liver disease from three different parts of China (Beijing, Shanghai and Hong Kong), 69% of genotype C patients in Hong Kong belonged to sub genotype Cs whereas 97% of genotype C HBV in Shanghai and Beijing belonged to subgenotype Ce ( $P < 0.0001$ ) [23].

31. Regarding HBV disease course, local studies suggested that patients infected with genotype C have a higher risk of cirrhosis and HCC development [21, 24], as well as more severe histological fibrosis [25]. A recent meta-analysis concluded that genotype C hepatitis B virus was associated with a higher risk of HCC than other major hepatitis B virus genotypes [26]. Among HBV genotype C, subgenotype Cs appears to carry a worse prognosis than subgenotype Ce [23]. In a local study by the Chinese University of Hong Kong, patients infected by subgenotype Cs had the lowest serum albumin and highest alanine aminotransferase levels compared with subgenotypes Ce and Ba. And, patients infected by subgenotype Cs also had more severe histological

necroinflammation than subgenotype Ce [23]. However, the meta-analysis did not find significant difference in the risk of HCC between HBV-infected patients with subgenotype Ce and Cs [26].

32. Nevertheless, in a study of end-stage HBV-related liver disease patients requiring transplantation, those with genotype B had significantly more pre-transplant acute flare and worse liver function while genotype C patients had a greater risk and severity of recurrence due to lamivudine-resistant mutants [27].

33. In a case control study, it was concluded that HCC patients had a significantly higher prevalence of core promoter mutations and genotype C but the association with HCC is mediated via the former [28]. A study of 5080 chronic HBV patients focusing on familial HCC found 22 such families, giving a prevalence of 4.3 families/1000 HBV carriers [29]. Age of onset of HCC is significantly younger in familial HCC than sporadic cases, and it progressively decreased down the generations, suggesting an anticipation phenomenon.

### **Hepatitis B Vaccination**

34. Occurrence of new HBV infection is dependent on the interplay of multiple factors, including size of HBV pool, proportion of susceptible population and chance of exposure to the virus. The universal vaccination programme for newborns, increased vaccination coverage in adults, practice of universal precaution in health care settings, screening of blood donors and promotion of safer sex all contributed to the reduced HBV incidence in Hong Kong. [30].

35. A 16-year follow up study of 1112 neonates born to HBsAg-positive mothers who received HBV vaccine and hepatitis B immunoglobulin at different schedules demonstrated the long term protective efficacy of immunisation [31]. Upon completion of the vaccination schedules, 92.6% developed antibody against surface antigen (anti-HBs) seroconversion. Thirty-nine (3.5%) babies were tested positive for HBsAg and had become chronic carriers, 35 of which (89.7%) occurred before one year of age. At the end of the 16<sup>th</sup> year, 610 subjects (54.9%) returned for blood test evaluation. Although the anti-HBs seroconversion rate dropped to 33.3% at the 16<sup>th</sup> year and a total of 90 (8%) vaccinees developed anti-HBc seroconversion, none was found to have breakthrough infection to become chronic HBV infection. At the 30<sup>th</sup> year of follow-up, 246 (22.1%) vaccinees returned for blood tests [32]. The anti-HBs

seroconversion rate was maintained at 37.4% at the 30<sup>th</sup> year. Although two and one subjects developed anti-HBc seroconversion at the 21<sup>st</sup> and 25<sup>th</sup> year respectively, there was no new development of HBsAg positivity detected. These findings demonstrated the long-term protective efficacy of neonatal hepatitis B immunization among high risk individuals up to at least 30 years. In another study comparing three different HBV vaccine regimens without boosters given to 318 HBV negative children recruited at age 3 months to 11 years and followed up annually, no subjects tested positive for HBsAg up to 18 years of follow up (88 subjects). A total of 88 anamnestic responses with significant increase in anti-HBs titers were documented in 70 subjects; 3 subjects had benign breakthrough HBV infection with isolated anti-HBc seroconversion [33].

36. Universal neonatal HBV vaccination programme has been in place in Hong Kong since 1988. The coverage rate for the birth dose of HBV vaccine among infants born locally from 2010 to 2017 was consistently above 99% (unpublished DH data). There is generally a slight decline in the coverage rate for the second or the third dose. The drop may be related to two factors: some local-births have returned to Mainland after delivery and did not attend MCHC for services, and some babies received the vaccine in the private sector instead of MCHC.

37. DH has been conducting immunisation coverage surveys (ICS) every two or three years starting from 2001 to determine immunisation the coverage rates of all vaccines, including HBV vaccination among children aged 2 to 5 years and attending pre-primary institutions including kindergartens and child care centers. Results from ICS conducted in 2001, 2003, 2006, 2009 and 2012 confirmed high coverage rates of hepatitis B vaccination [34, 35, 36]. In the latest round of ICS conducted in 2015 (unpublished DH data), a total of 8723 children enrolled in 51 pre-primary institutions participated in the survey, reaching an overall response rate of 81.3%. Similar to previous years, the 2015 survey demonstrated a satisfactorily high coverage rate of HBV vaccination (Box 44).

38. Apart from universal neonatal HBV vaccination programme, supplementary Primary 6 vaccination programme was introduced in 1998. The coverage rate for three doses of HBV vaccine had been consistently above 99% in the past decade but showed a slight decline in 2015/16 to 97.9% for the third dose. Of note, this coincided with a change of survey methodology in 2015 and an underestimation of the actual coverage was possible (Box 45). With a high coverage of the neonatal HBV

vaccination programme, the number of Primary 6 students eligible for HBV vaccination continued to decrease in the past decade (from 17 171 in 2000/01 to 707 in 2016/17). The number of students who did not receive the third dose vaccination remained stable at a few hundred per year.

39. In 2009, a HBsAg seroprevalence study was conducted among 1913 children aged 12 to 15 years (unpublished DH data). The study found an HBsAg seroprevalence of 0.78% (95% confidence interval 0.39-1.16%, [Box 46](#)) in these children who were born after the implementation of universal neonatal HBV vaccination programme. This result showed that Hong Kong had already achieved a time-bound goal of reducing chronic HBV infection rate to less than 2% among 5 year-old children by the year of 2012, as set by the Western Pacific Regional Office (WPRO) of the WHO. In July 2011, Hong Kong was verified by WPRO as having successfully achieved the goal of HBV control. Based on the same study findings, Hong Kong was also verified as of June 2013 as having met the goal of achieving a seroprevalence of less than 1%.

40. In the CRPVH 2001 study, about 16% of the telephone-interviewed subjects reported a history of HBV vaccination, with a higher frequency in persons below 50 years of age. Some 83% of them reported having completed the vaccination course. Over 99% had the cost paid by them or borne by their employers. In another recent local survey by face-to-face questionnaire interview on over 1900 adult Chinese, fifty-eight percent (n=1151) of the subjects had been tested for HBV during adulthood. Among those tested negative for HBV infection, fifty-eight percent (n=506) of them reported subsequent HBV vaccination [37]. Age, occupation, having children, and family monthly income, were independent factors associated with vaccination in the study. Overall, the persistent significant level of HBsAg seroprevalence in the local population, though declining, means a significant disease burden in the years to come.

### **Current Situation of Hepatitis C**

41. From 2002 to 2017, a total of 127 cases of acute hepatitis C infection were reported to DH under the statutory notification system ([Box 1](#)), with one to fourteen cases reported annually from 2002 to 2015, and a record high of 39 cases in 2016. A review by the Centre for Health Protection entitled “Hepatitis C in Hong Kong, 2008 to 2011” [38] showed that among the 22 laboratory confirmed acute hepatitis C cases reported to DH from January 2008 to October 2011, there were 17 males and 5

females, most (86%) acquired the infection locally. The median age was 47.5 years. Majority (86%) was ethnic Chinese. Five (23%) of them reported history of injecting drug use while no particular risk factor was identified for the remaining cases.

42. Of the 39 cases in 2016, 31 were male (79%), with age ranged from 23 to 94 years (median: 42 years). Thirteen (33%) required hospitalisation and no fatalities were recorded. With regard to the potential risk exposures, one case reported having tattoo procedure and two cases were identified as injecting drug users. Two cases reported to have sexual partners who were HCV carriers. Among the 31 male cases reported, 23 (74%) were known men who have sex with men. There was also one case who had history of repeated hospital admissions and had received multiple transfusions of blood product during the incubation period. Epidemiological investigation and contact tracing did not identify other acute hepatitis C cases and the source of infection in this case could not be determined. For the rest of the cases, no epidemiological linkage was identified and all cases were regarded as sporadic. There have been overseas reports of rising incidence of sexual transmission of HCV among men who have sex with men [39]. Further study and monitoring is required of the possibility that this is also the case for Hong Kong.

43. Although HCV shares similar transmission routes with hepatitis B, the epidemiology of two infections are different in Hong Kong. While HBV is still prevalent in many populations in Hong Kong, HCV prevails only in isolated communities.

44. Data from new blood donors who were mostly adolescents and young adults in the last decade suggested that HCV prevalence was around 0.1% locally, with the figure in 2017 being 0.06% (95% confidence interval; 0.03 - 0.08%) (Box 47). Findings of the household study of the entire spectrum of adult age groups conducted in 2001 further supported the uncommon occurrence of HCV infection among general population in Hong Kong; the overall positive rate was 0.3% in 936 subjects (95% confidence interval, 0.07%-0.94%) (Box 49). From 1999 to 2016, 10 of 2294 (0.4%) clients who attended the Therapeutic Prevention Clinic (TPC) at Integrated Treatment Centre (ITC) of CHP, DH for post-exposure management were tested positive for anti-HCV. Nine (90%) cases were non-HCW and all cases were already HCV infected at time of injury (Box 50).

45. From studies published in the early 1990s, it was shown that anti-HCV was more commonly found in injecting drug users (IDU, 66.8%), haemophilia (56%), haemodialysis (4.6%) and other patients requiring frequent blood/blood product

transfusions but not persons at risk through sexual contact [40]. In a more recent analysis of HCV positive blood donors, of those with identifiable risk factors, history of blood transfusion (43.7%) was the most common risk factor, followed by intravenous drug use (34.9%) and tattoo (28.6%). The source of infection was unknown in more than half of the respondents in the study [41].

46. A survey in 2011 of haemophiliacs under local public care found 100 of 222 patients (45%) infected with hepatitis C [42]. Another study conducted for 51 haemodialysis patients found that 8 (16%) were positive for anti-HCV by second generation enzyme immunoassay and 1 (2%) for HCV RNA alone, giving an overall infection rate of 18% [43]. This study also found a new infection rate of 4.9% per patient-year upon longitudinal follow up of 19 months.

47. Injecting drug use has been an important route of HCV acquisition. Results of testing non-random samples from drug users under treatment showed a HCV positive rate of 74% in 1988/1989 and 46% in 2000/2001 (Box 51). An HCV seroprevalence study in 2006 conducted in methadone clinics targeting IDU echoed the high prevalence rate of HCV in this community [44]. Of 567 IDU participants recruited in 2006, the prevalence of anti-HCV was 85% (95% confidence interval 82.5 – 88.3%). Another study in 2011 involving 622 IDU recruited at their gathering places found a similar figure of 81.7% (95% confidence interval 78.6 - 84.7%) infected with HCV [45]. In this study, the majority (84.7%) were male with a median age of 53 years. The median heroin injection duration was 25 years. Injection duration, current or recent injection, ever sharing injecting equipment and concomitant use of other drugs e.g. midazolam were independent factors associated with HCV infection in the two studies. In the recent New Life New Liver Project, which provided targeted HCV screening and education to ex-IDU in the community, 56% of 234 subjects screened were HCV positive. The number needed to screen to detect one patient with positive HCV was 1.8 (95% confidence interval 1.6-2.0) [46].

48. HIV/AIDS patients, with a proportion being IDU, is another group with consistent data showing a comparatively high HCV prevalence (Box 52, 53). From 2000 to 2017, HCV/HIV coinfection among new patients attending ITC ranged from 1.5% to 24.8%. The decreasing trend of anti-HCV seroprevalence was largely attributed to the decreasing proportion of new patients acquiring HIV via injecting drug use. The prevalence rate appears to be higher in male than female patients, likely related to the differential risk of parenteral and blood product exposure (Box 52). While HCV

infection was present in 1.7–6.3% of HIV/AIDS patients infected due to sexual contact, HCV was nearly universal in patients infected through drug injection (Box 53). It should be noted that, among male patients who acquired HIV via heterosexual contact and tested anti-HCV positive, 60.0% (30 out of 50 subjects) had a past history of injecting drug use (Box 53). Among those heterosexual male HIV infected patients without history of injecting drug use, the prevalence of anti-HCV was 3%.

49. There has been overseas data supporting sexual transmission of HCV among HIV-infected men who have sex with men [47]. The anti-HCV prevalence of subjects who contracted HIV via homosexual or bisexual contact in the ITC HIV/AIDS patient cohort has remained below 2% from screening since 2005. However, this figure has shown an increasing trend since 2012 with the number of individuals with HCV/HIV coinfection at the time of HIV diagnosis rising from 16 (1.3%) in 2013, to 50 (2.1%) in 2017 (Box 53).

50. From July to November 2013, ITC identified seven cases of recent HCV infection in Chinese HIV-infected MSM [48]. Five of the seven cases were also diagnosed to have recent syphilis infection during the period. None of them had history of injecting drug use. Phylogenetic analyses revealed that all cases belonged to the same genotype (genotype 3) although investigation showed no apparent linkage on their sexual exposure. An analysis on HIV-infected MSM attending ITC who had HCV seroconversion in the period 1999-2013 was subsequently performed [49]. Fourteen (1.1%) patients seroconverted, with an overall incidence rate of 0.22 per 100 patient-years. The incidence rate increased from 0.13 per 100 patient-years before 2002 to 0.19 per 100 patient years in 2002-2007 and 0.47 per 100 patient-years in 2008-2013. Genotype 3 was most commonly detected. Compared with the non-seroconverters, the seroconverters were of higher education level and had prior history of sexually transmitted infection. The overall higher HCV prevalence, and the increasing incidence of HCV among HIV-positive MSM, coupled with the hastened liver disease progression in HIV-infected patients [50], would no doubt result in a unique HCV/HIV coinfection that demands further attention.

51. Since 2003, laboratory surveillance for HCV in Hong Kong was enhanced to monitor the trend of anti-HCV among selected population groups, including blood donors from HKRCBTS, and selected in-patients from the Princess Margaret Hospital (PMH) and Prince of Wales Hospital (PWH, joined since 2005). Some 180,000-260,000 new and repeated blood donors of HKRCBTS were tested for anti-HCV each

year, among which the prevalence was consistently low at less than 0.1% since 2003. Whereas among the selected hospital patients tested in the past eleven years, the overall anti-HCV prevalence was 2.3% (Box 54). Anti-HCV was most commonly found in drug users, of which 51.8% were found positive, followed by patients with history of blood transfusion at 9.0%. Overall, the male-to-female ratio of HCV positive subjects was about 2.3 to 1, with a mean age of 51.4 years old (Box 55).

### Genotypes of Hepatitis C

52. Genotypic studies in Hong Kong has identified that 1b and 6a were the prevalent HCV genotypes locally, a scenario different from that in western countries where 1a predominated [51]. In an early study of 212 blood donors tested anti-HCV positive from 1991 to 1994, the commonest genotype found was 1b (58.8%), followed by 6a (27.0%) [52]. In another study of hospitalized patients with HCV testing for clinical indications 1b was the commonest type found in patients with chronic liver diseases and chronic renal failure [53]. According to a local study of patients on renal replacement therapy, the predominant genotype was 1b, followed by 1a and 6a [54]. Yet, the commonest genotype in intravenous drug users was genotype 6. A retrospective analysis of 106 intravenous drug users and 949 non-drug users with samples collected between December 1998 and May 2004 also confirmed the significant high prevalence of genotype 6a in drug users (58.5%) followed by 1b (33.0%), in contrast to 63.6% for 1b and 23.6% for 6a in non-drug users [55]. Besides intravenous drug use, age and sex were independent factors associated with HCV genotypes in this study. In a methadone clinic-based study published in 2011, out of 273 IDUs with different periods of initiating injection, 52% had genotype 6a and 38% had 1b. Both genotypes 1b and 6a were prevalent among older injectors, while subtype 3a was more common in young injectors and those initiating injection more recently during 1995-2006. Moreover, phylogenetic analysis revealed no specific clustering of any subtype or genotype, which did not suggest any outbreak of HCV among the study population. The extensive use of methadone widely available since 1980s may have protected Hong Kong from the emergence of HCV clusters among injection drug users [56].

53. For the HIV-infected MSM attending ITC who were diagnosed with acute HCV infection between 2009 to 2014, genotype 3a was the most prevalent (63.6%), followed by 1a (18.2%) and 6a (9.1%). The high prevalence of genotype 3a in MSM was in stark contrast to its rarity among HCV-infected IDU in Hong Kong. Phylogenetic analyses revealed a monophyletic HCV-3a cluster with members all diagnosed

between 2013 and 2014, and a homologous pair with HCV-6a genotype. However, there was no temporal or genetic clustering of the corresponding HIV sequences [57].

54. The natural history of 138 HCV genotype 1 patients (median age: 50 years) was compared with that of 78 HCV genotype 6 patients (median age: 46.5 years) in Queen Mary Hospital [58]. Both genotypes share a similar natural history based on liver biochemistry, HCV viral load, and probability of cirrhotic complications and mortality after a median follow-up period of over 5 years.

### **Liver Cancer – Major Morbidity and Mortality from Viral Hepatitis**

55. Chronic HBV and HCV infection are important risk factors for cirrhosis and liver cancer. Globally 788 000 people died of liver cancer in 2015, and HBV and HCV accounted for approximately 80% of liver cancer cases [59]. Local studies showed that 75-80% of hepatocellular cancers in Hong Kong were related to chronic HBV infection, and 3-6% cases were related to chronic HCV infection. HBV and HCV co-infection accounted for another 0.4-3% [60]. Among 76 liver transplants performed in Queen Mary Hospital due to cirrhosis from 1999 to 2000, 51 and 7 were related to hepatitis B and C respectively [61].

56. Apart from chronic HBV and HCV infection, other risk factors for liver cancer include excessive alcohol consumption and consumption of aflatoxin contaminated food. In Hong Kong, the age-standardised incidence rate and death rate of liver cancer is higher in male.

57. According to the data from the Hong Kong Cancer Registry [62], liver cancer, including neoplasm of liver and intrahepatic bile ducts, was the fourth commonest cancer in men and tenth commonest cancer in women in 2016. There were 1810 new registered cases of liver cancer, with 1391 cases of males and 419 cases of females (male to female ratio was about 3.3 to 1). There was a downward trend for the age-standardized incidence rate for both male and female in the past decade (Box 57). The figures were 23 for male and 5.7 for female per 100 000 standard population in 2016.

58. In 2016, liver cancer was the third leading cause of cancer deaths in Hong Kong. There were 1540 registered mortality from liver cancer. There was a downward trend for the age-standardized mortality rate for both sexes in the past decade (Box 59). The figures were 18 for male and 4.9 for female per 100 000 standard population in 2016 [62].

# SURVEILLANCE OF VIRAL HEPATITIS IN HONG KONG

## 2017 UPDATE

### Acute viral hepatitis under the disease notification system

#### Tabulated results

| Box                         | Title  | Page |
|-----------------------------|--|------|
| Box 1.                      | Number of cases of viral hepatitis reported to the Department of Health between 1974 and 2017 (Data source: CHP, DH) | 24   |
| Box 2.                      | Reported cases of viral hepatitis from 1966 to 2017 (Data source: CHP, DH)   | 25   |
| Box 3.                      | Breakdown of viral hepatitis by aetiology reported from 1996 to 2017 (Data source: CHP, DH)                          | 26   |
| <a href="#">Hepatitis A</a> |  |      |
| Box 4.                      | Number of hepatitis A cases reported from 2003 to 2017 (Data source: CHP, DH)  | 27   |
| Box 5.                      | Sex distribution of hepatitis A cases reported from 2003 to 2017 (Data source: CHP, DH)                              | 28   |
| Box 6.                      | Age distribution by proportion of reported cases of hepatitis A, 1989-2017 (Data source: CHP, DH)                    | 29   |
| Box 7.                      | Notification rates and death rates of hepatitis A, 1988 - 2017 (Data source: CHP, DH)                                | 30   |
| <a href="#">Hepatitis B</a> |  |      |

**Box 2. Reported cases of viral hepatitis from 1966 to 2017 (Data source: CHP, DH)**

**Case definition:**

Hepatitis A – positive for anti-HAV IgM  
 Hepatitis C – positive for anti-HCV

Hepatitis B – positive for anti-HBc IgM  
 Hepatitis E - positive for anti-HEV

**Box 3. Breakdown of viral hepatitis by aetiology reported from 1996 to 2017 (Data source: CHP, DH)**

## HEPATITIS A

Box 4. Number of hepatitis A cases reported from 2003 to 2017 (Data source: CHP, DH)

## HEPATITIS A

Box 5. Sex distribution of hepatitis A cases reported from 2003 to 2017 (Data source: CHP, DH)

# HEPATITIS A

Box 6. Age distribution by proportion of reported cases of hepatitis A, 1989-2017 (Data source: CHP, DH)

Year

# HEPATITIS A

Box 7. Notification rates and death rates of hepatitis A, 1988 - 2017 (Data source: CHP, DH)

## HEPATITIS B

Box 8. Number of hepatitis B cases reported from 1995 to 2017 (Data source: CHP, DH)

## HEPATITIS B

Box 9. Sex distribution of hepatitis B cases reported from 1995 to 2017 (Data source: CHP, DH)

## HEPATITIS B

Box 10. Age distribution of hepatitis B cases reported from 1995 to 2017 (Data source: CHP, DH)

## HEPATITIS C

Box 11. Number of hepatitis C cases reported from 2002 to 2017 (Data source: CHP, DH)

## HEPATITIS C

Box 12. Sex distribution of hepatitis C cases reported from 2005 to 2017 (Data source: CHP, DH)

# HEPATITIS C

Box 13. Age distribution of hepatitis C cases reported from 2005 to 2017 (Data source: CHP, DH)

## HEPATITIS E

Box 14. Number of reported hepatitis E cases reported from 1996 to 2017 (Data source: CHP, DH)

## HEPATITIS E

Box 15. Mean and median plot of reported cases of hepatitis E by month from 1997 to 2017 (Data source: CHP, DH)

## HEPATITIS E

Box 16. Sex distribution of hepatitis E cases reported from 1996 to 2017 (Data source: CHP, DH)

# HEPATITIS E

Box 17. Age distribution by proportion of reported cases of hepatitis E from 1996 to 2017 (Data source: CHP, DH)

# HEPATITIS E

**Box 18. Notification rates and death rates of hepatitis E from 1996 to 2017 (Data source: CHP, DH)**

### Seroprevalence of hepatitis A and hepatitis E

#### Tabulated results

| <b>Box</b> | <b>Title</b>  | <b>Page</b> |
|------------|---|-------------|
| Box 19.    | Prevalence of anti-HAV in a collection of studies/testing between 1978 and 2009 (Data sources: Multiple sources)  | 43          |
| Box 20.    | Prevalence of anti-HAV in participants of Community Research Project for Viral Hepatitis (CRPVH) 2001 (Data source: DH)                                 | 44          |
| Box 21.    | Prevalence of anti-HAV in individuals with blood collected for serological diagnosis of conditions unrelated to hepatitis (Data source: PHLSB, CHP, DH) | 44          |
| Box 22.    | Prevalence of anti-HAV at baseline screening of HIV/AIDS patients attending ITC from Jul 2007 to 2017 (Data source: ITC, CHP, DH)                       | 45          |
| Box 23.    | Prevalence of anti-HAV per HIV risk at baseline screening of HIV/AIDS patients attending ITC from Jul 2007 to 2017 (Data source: ITC, CHP, DH)          | 46          |
| Box 24.    | Prevalence of anti-HEV in participants of Community Research Project for Viral Hepatitis (CRPVH) 2001 (Data source: DH)                                 | 47          |

| Total                         | 3756       | 1928 (51.3%)     |

## HEPATITIS E

### Box 24. Prevalence of anti-HEV in participants of Community Research Project for Viral Hepatitis (CRPVH) 2001 (Data source: DH)

| Age group | No. Tested | Anti-HEV +ve (%) |
|-----------|------------|------------------|
| 18-29     | 137        | 11 (8.0%)        |
| 30-39     | 222        | 32 (14.4%)       |
| 40-49     | 290        | 70 (24.1%)       |
| 50-59     | 170        | 39 (22.9%)       |
| 60 & over | 115        | 24 (20.9%)       |
| All       | 934        | 176 (18.8%)      |

# SURVEILLANCE OF VIRAL HEPATITIS IN HONG KONG

## 2017 UPDATE

### Seroprevalence and vaccination coverage of hepatitis B

#### Tabulated results

| Box     | Title  | Page |
|---------|--|------|
| Box 25. | Prevalence of HBsAg in new blood donors from 1990 to 2017 (Data source: HKRCBTS)   | 50   |
| Box 26. | HBsAg prevalence and its sex and age breakdown in new blood donors in 2017 (Data source: HKRCBTS)  | 51   |
| Box 27. | HBsAg prevalence among university students/staff (Data source: City University Health Centre (till 2002), Baptist University Health Centre (2001 to 2009) & Lingnan University Health Service (2003 and 2004)) | 51   |
| Box 28. | HBsAg prevalence from the FPAHK's Clinical Services (Data source: FPA)   | 52   |
| Box 29. | HBsAg prevalence in antenatal women from 1990 to 2017 (Data source: FHS and PHLSB, CHP, DH)  | 53   |
| Box 30. | HBsAg prevalence and age breakdown of antenatal mothers from 1990 to 2017 (Data source: FHS, DH)   | 54   |
| Box 31. | Number of antenatal mothers with positive HBsAg by age, from 1990 to 2017 (Data source: FHS, DH)   | 55   |
| Box 32. | Prevalence of hepatitis B markers in police officers, by sex from 1996 to 2006 and 2012 to 2017 (Data source: DH)  | 56   |
| Box 33. | Prevalence of hepatitis B markers in police officers, by age from 1996 to 2006 and 2012 to 2017 (Data source: DH)  | 58   |
| Box 34. | Prevalence of HBsAg from the Community Research Project on Viral Hepatitis (CRPVH) 2001 (Data source: DH)  | 59   |
| Box 35. | Prevalence of HBsAg in newly recruited health care workers of DH from 2001 to 2017 (Data source: DH)   | 60   |
| Box 36. | HBsAg prevalence among tuberculosis patients treated at chest clinics from 2005 to 2015 (March to May) (Data source: TB and Chest Service, CHP, DH)  | 61   |
| Box 37. | HBsAg prevalence, stratified by age, among tuberculosis patients treated at chest clinics from 2005 to 2015 (March to May) (Data source: TB and Chest Service, CHP, DH)  | 62   |
| Box 38. | Prevalence of hepatitis B markers in persons attending Therapeutic Prevention Clinic of Integrated Treatment Centre (ITC) for post-exposure management, from July 1999 to 2016 (Data source: ITC, CHP, DH)     | 63   |
| Box 39. | Prevalence of hepatitis B markers in drug users from 1990 to 2010 (Data source: PHLSB, CHP, DH)  | 64   |

|         |  |    |
|---------|--|----|
| Box 40. | Prevalence of HBsAg at baseline screening of HIV/AIDS patients attending ITC from 2000 to 2017 (Data source: ITC, CHP, DH)                               | 65 |
| Box 41. | Prevalence of HBV infection per HIV risk at baseline screening of HIV/AIDS patients attending ITC from 2000 to 2017 (Data source: ITC, CHP, DH)          | 66 |
| Box 42. | HBsAg prevalence (%) in new blood donors, pre-marital screening and antenatal women from 1990 to 2017 (Data source: multiple sources)                    | 67 |
| Box 43. | HBsAg prevalence (%) in other selected populations from 1990 to 2017 (Data source: multiple sources)   | 68 |
| Box 44. | Hepatitis B immunisation coverage rates among children aged 2 to 5 by year of birth (Data source: ref 34, 35, 36 & unpublished DH data)                  | 69 |
| Box 45. | Cumulative statistics of the supplementary hepatitis B vaccination programme for Primary 6 students from the school years 2000 to 2017 (Data source: DH) | 70 |
| Box 46. | HBsAg seroprevalence by age among children aged 12 to 15 years in 2009 (Data source: unpublished data of DH)   | 71 |

## HEPATITIS B

Box 25. Prevalence of HBsAg in new blood donors from 1990 to 2017 (Data source: HKRCBTS)

## HEPATITIS B

**Box 26. HBsAg prevalence and its sex and age breakdown in new blood donors in 2017 (Data source: HKRCBTS)**

| Age Group | Male       |               | Female     |               |
|-----------|------------|---------------|------------|---------------|

## HEPATITIS B

Box 46. HBsAg seroprevalence by age among children aged 12 to 15 years in 2009 (Data source: unpublished data of DH)

### Seroprevalence of hepatitis C

#### Tabulated results

| Box     | Title   | Page |
|---------|---|------|
| Box 47. | Anti-HCV prevalence in new blood donors, 1991 to 2017 (Data source: HKRCBTS)  | 73   |
| Box 48. | Anti-HCV prevalence and its sex and age breakdown in new blood donors in 2017 (Data source: HKRCBTS)  | 74   |
| Box 49. | Prevalence of anti-HCV in participants of Community Research Project on Viral Hepatitis (CRPVH) 2001 (Data source: DH)  | 75   |
| Box 50. | Prevalence of anti-HCV at baseline screening of injured persons attending Therapeutic Prevention Clinic of Integrated Treatment Centre (ITC), from July 1999 to 2016 (Data source: ITC, CHP, DH)  | 75   |
| Box 51. | Prevalence of anti-HCV in drug users on rehabilitation (Data source: PHLSB, CHP, DH)  | 76   |
| Box 52. | Prevalence of anti-HCV at baseline screening of HIV/AIDS patients attending ITC from 2000 to 2017 (Data source: ITC, CHP, DH)   | 76   |
| Box 53. | Prevalence of anti-HCV per HIV risk at baseline screening of HIV/AIDS patients attending ITC from 2000 to 2017 (Data source: ITC, CHP, DH)  | 77   |
| Box 54. | Prevalence of anti-HCV from screening of blood donors and clinical testing of patients in 2 hospital clusters under Hospital Authority from 2007 to 2017 (Data source: HKRCBTS, PMH Microbiology Laboratory, PWH Microbiology Laboratory) | 78   |
| Box 55. | Characteristics of anti-HCV positive subjects detected at HKRCBTS and 2 hospital clusters under Hospital Authority from 2005 to 2017 (Data source: HKRCBTS, PMH Microbiology Laboratory, PWH Microbiology Laboratory)                     | 79   |

# HEPATITIS C

Box 47. Anti-HCV prevalence in new blood donors, 1991 to 2017 (Data source: HKRCBTS)

## HEPATITIS C

**Box 48. Anti-HCV prevalence and its sex and age breakdown in new blood donors in 2017 (Data source: HKRCBTS)**

| Age Group | Male       |                  | Female     |                  |
|-----------|------------|------------------|------------|------------------|
|           | No. tested | Anti-HCV +ve (%) | No. tested | Anti-HCV +ve (%) |
| 16-19     | 6667       | 1 (0.01%)        | 8366       | 1 (0.01%)        |
| 20-29     | 3770       | 1 (0.03%)        | 4220       | 0 (0.00%)        |
